... La nota G estaba dedicada a los **números de Bernoulli**; en este apartado Ada describe con detalle las operaciones mediante las cuales las tarjetas perforadas "tejerían" una secuencia de números en la máquina analítica. Este código está considerado como el primer algoritmo específicamente diseñado para ser ejecutado por un ordenador, aunque nunca fue probado ya que la máquina nunca llegó a construirse. (Wikipedia)

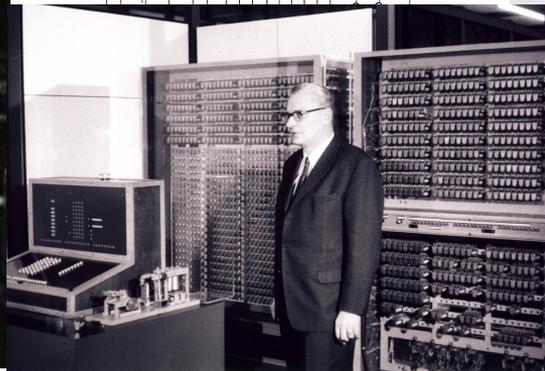

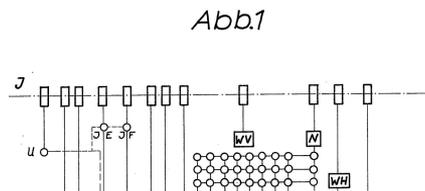

En 1935 Zuse construye la Z1. Leía las instrucciones desde una cinta perforada de 35 mm. No era una máquina Turing completa

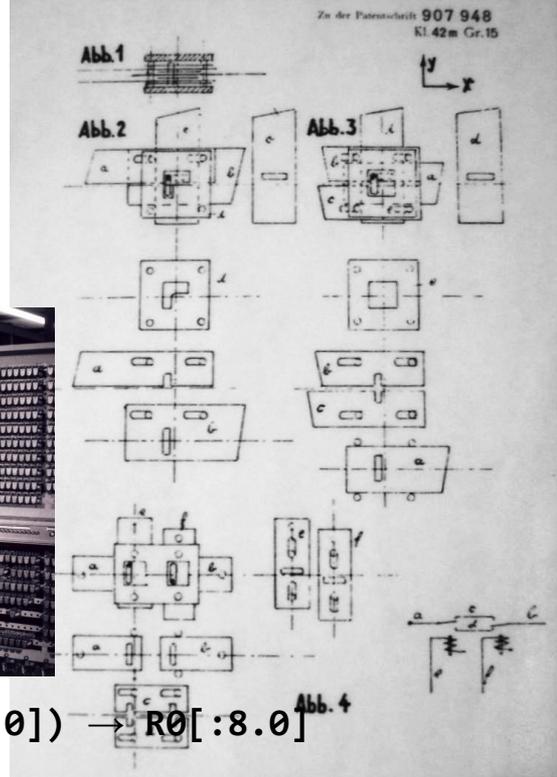

The Henschel Hs 129B ground attack aircraft

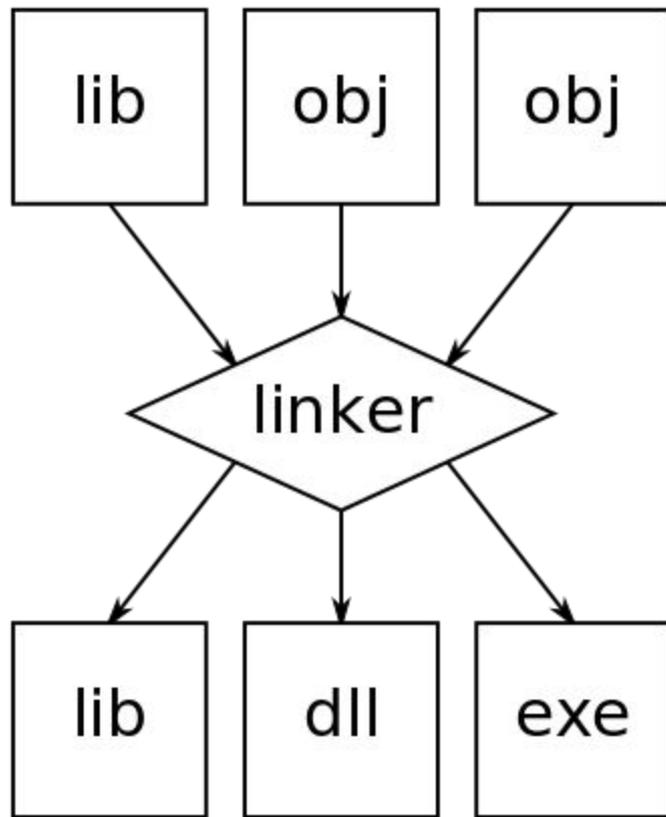

Zu der Patentschrift: 924 107  
Kl.42m Gr.15

P2 max (V0[:8.0], V1[:8.0]) → R0[:8.0]  
 V0[:8.0] → Z1[:8.0]  
 (Z1[:8.0] < V1[:8.0]) → V1[:8.0] → Z1[:8.0]  
 Z1[:8.0] → R0[:8.0]  
 END

La Z3 (1941) era un computador binario de punto flotante de 22 bits con memoria y unidad de cálculo basada en relés telefónicos. No almacenaba el programa en memoria. A pesar de la ausencia de saltos condicionales, el Z3 era un ordenador Turing-completo

Rear Admiral (then Commodore) Grace M. Hopper, 1984. By 1952, Hopper had finished her program linker. The term compiler was coined by Hopper. It was written for the A-0 System.

## The Phases of a Translator

A programming language translator usually consists of a sequence of stages

Lexer:

- Skips the comments and whitespaces and produces the stream of tokens for numbers, identifiers, reserved words, etc

Parser:

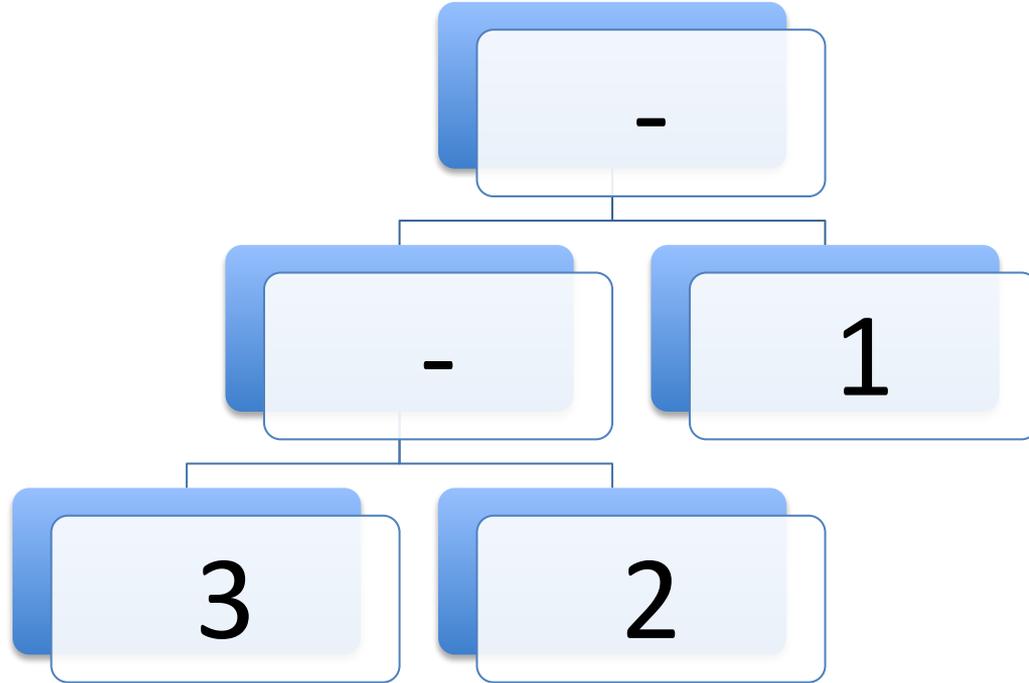

- Reads the stream of tokens, check that it complies with the syntactic rules and produces the *Abstract Syntax Tree*: a data structure representing the underlying syntactic structure of the input program

This tool, a parser generator uses a parsing algorithm known as LALR that was invented by Donald Ervin Knuth (1965)

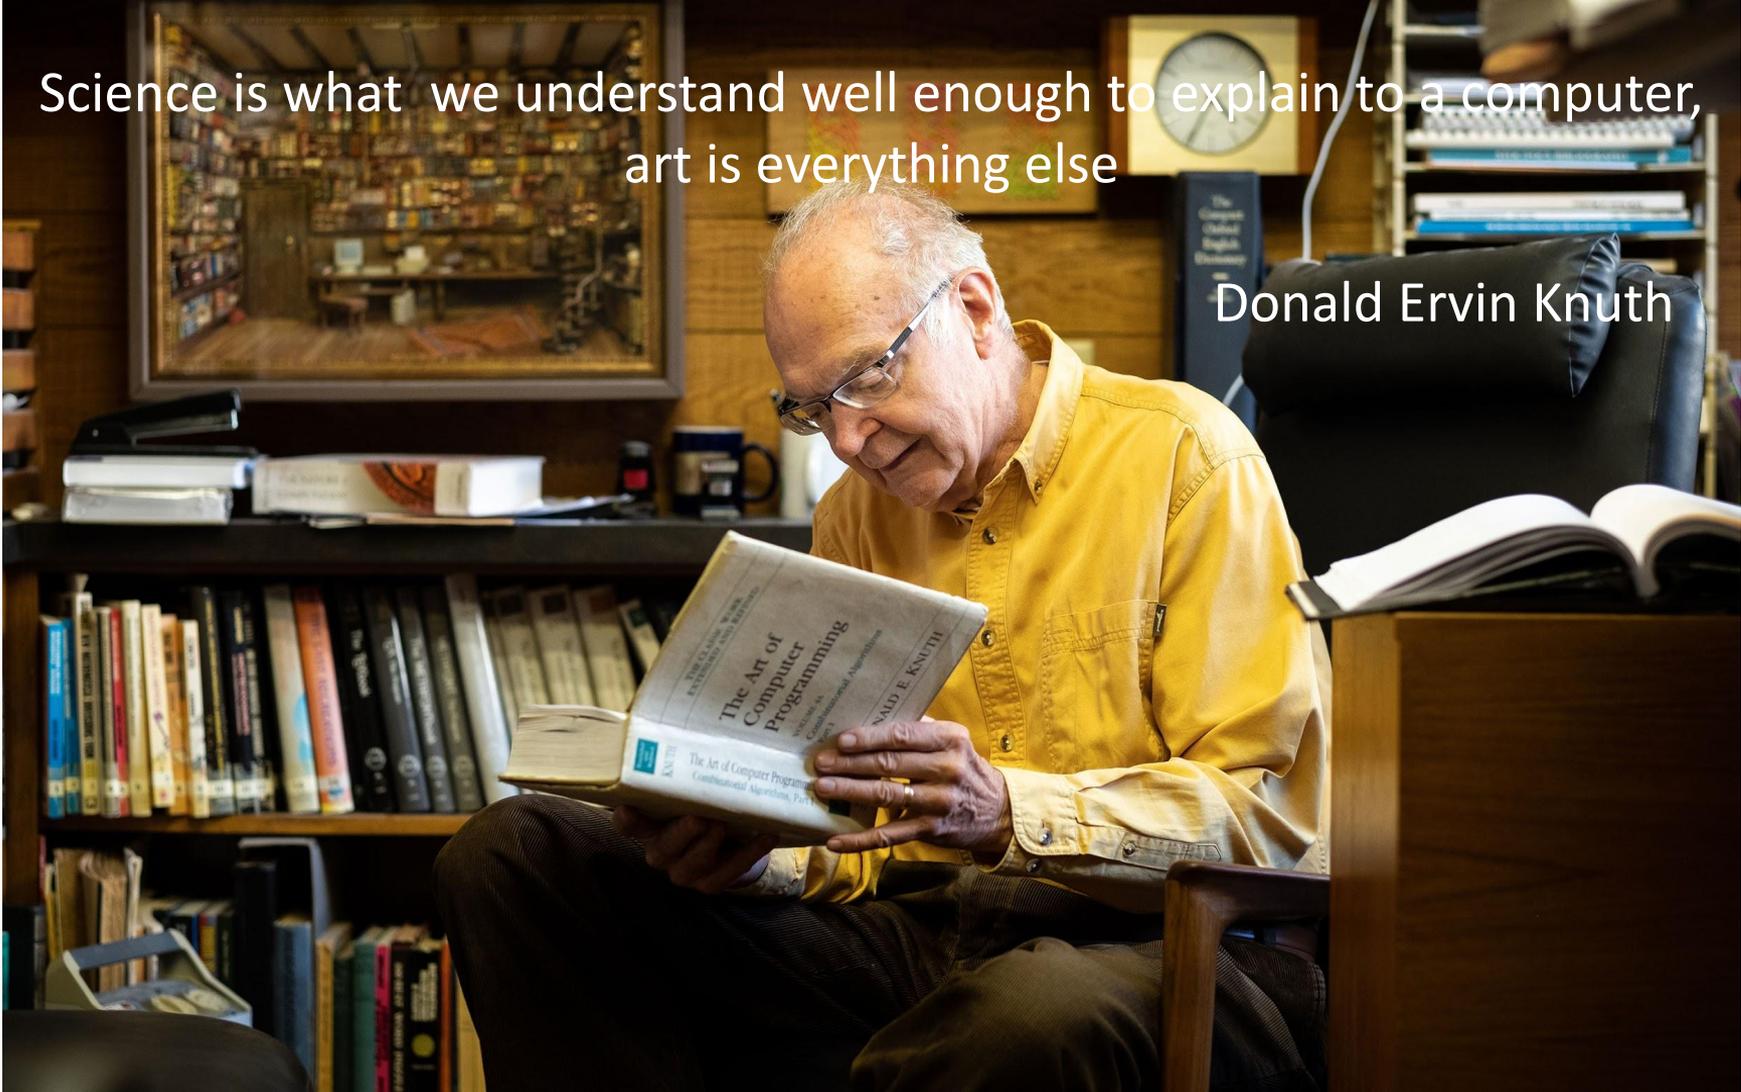

If you think you're a really good programmer... read Knuth's Art of Computer Programming... You should definitely send me a resume if you can read the whole thing.

— Bill Gates —

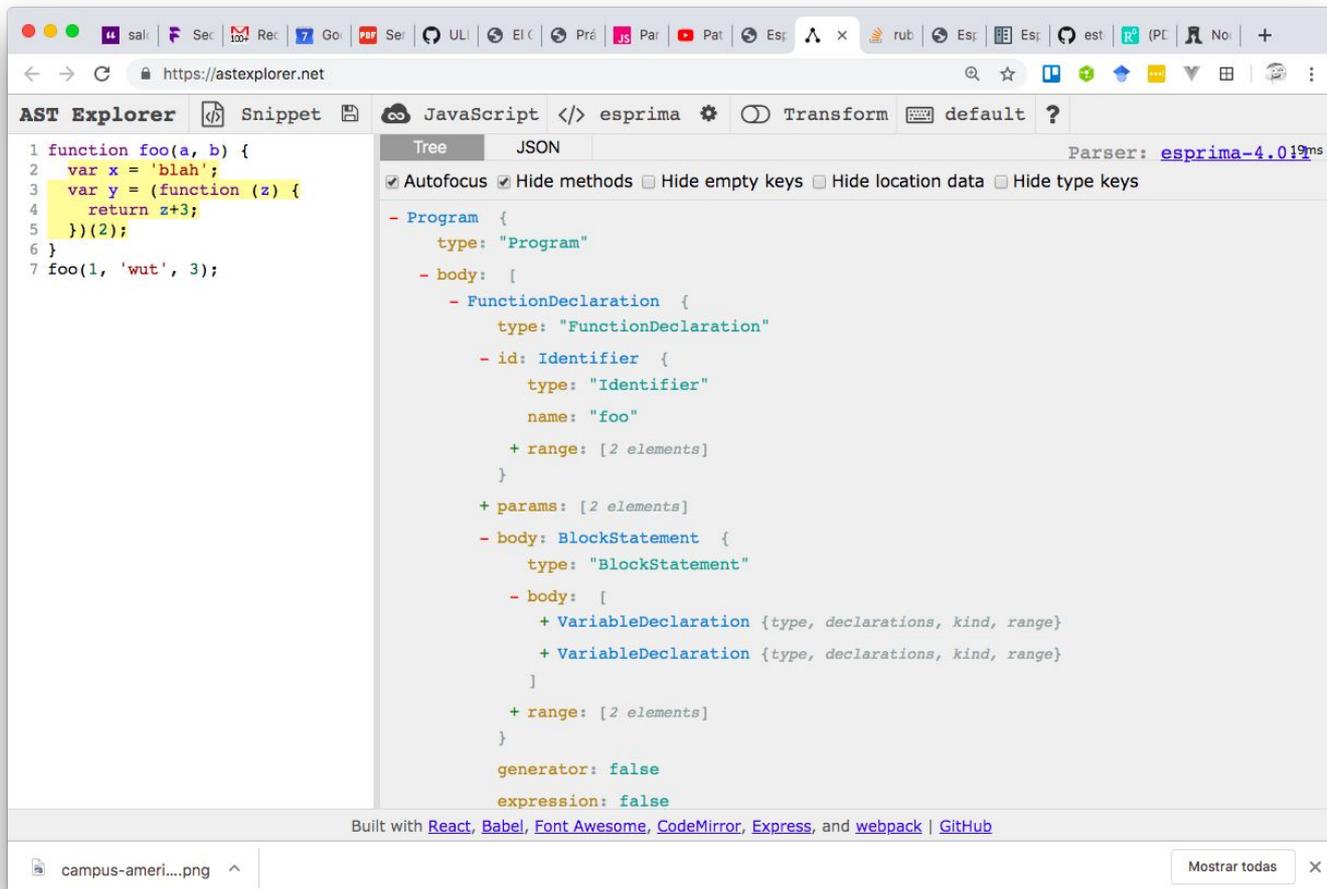

AZ QUOTES

Science is what we understand well enough to explain to a computer,  
art is everything else

Donald Ervin Knuth

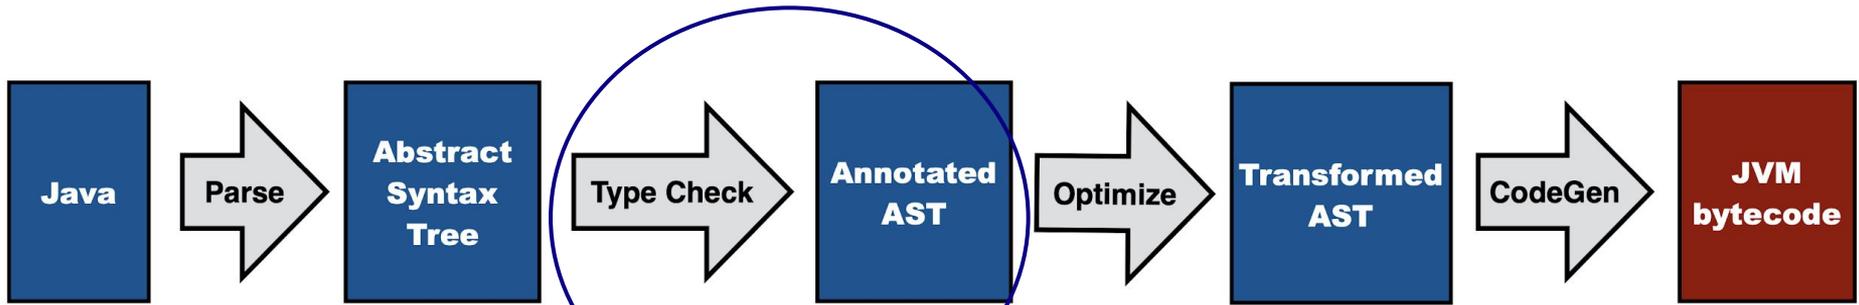

The *Abstract Syntax Tree*: a data structure representing the underlying syntactic structure of the input program: <https://astexplorer.net/>

The screenshot shows the AST Explorer interface. On the left, the source code is displayed with line numbers 1 through 7. The code is a function named 'foo' that takes two arguments, 'a' and 'b'. Inside the function, there is a variable declaration 'var x = \'blah\';', a nested function declaration 'var y = (function (z) { return z+3; })(2);', and a final call to 'foo(1, \'wut\', 3);'. The third line is highlighted in yellow.

On the right, the AST is shown in a tree view. The root node is 'Program', which has a 'body' array containing a 'FunctionDeclaration' node. This 'FunctionDeclaration' node has an 'id' of 'foo', 'params' of 'a, b', and a 'body' array containing a 'BlockStatement' node. The 'BlockStatement' node has a 'body' array with three elements: a 'VariableDeclaration' for 'x', a 'FunctionExpression' (represented as a 'BlockStatement' in the tree view) for the nested function, and a 'CallExpression' for the final function call. The tree view also shows various metadata like 'range' and 'generator'.

At the bottom of the interface, there is a footer that reads: "Built with [React](#), [Babel](#), [Font Awesome](#), [CodeMirror](#), [Express](#), and [webpack](#) | [GitHub](#)".

- Receives as input the abstract syntax tree
- Checks that the program complies with the static semantic rules of the language
- Performs name analysis, relating uses of names to declarations of names
- Checks that the types of arguments of operations are consistent with their specification

### Input Program

```

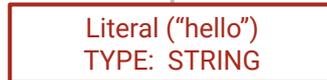

let a : integer;
a = "hello";
  
```

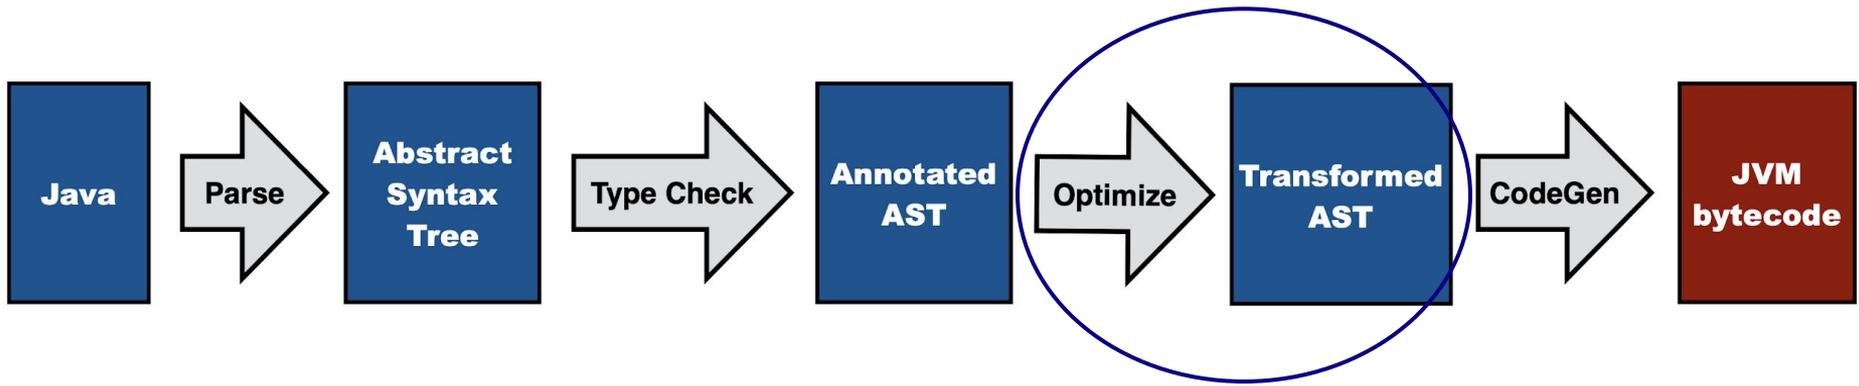

### AST

### Symbol Table

ID	TYPE
a	INTEGER

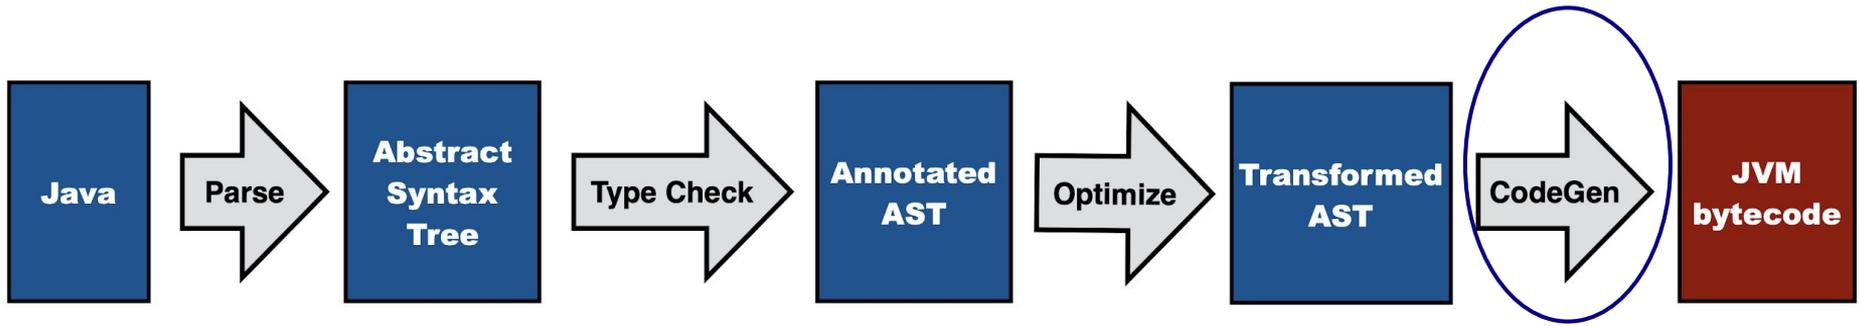

- Applies transformations that improve the program in various goals
- Goals: execution time, memory consumption, energy consumption, etc.
- Examples of transformations: Constant folding, Constant propagation, Loop invariants

### Input Program

```
a = 2+3;
```

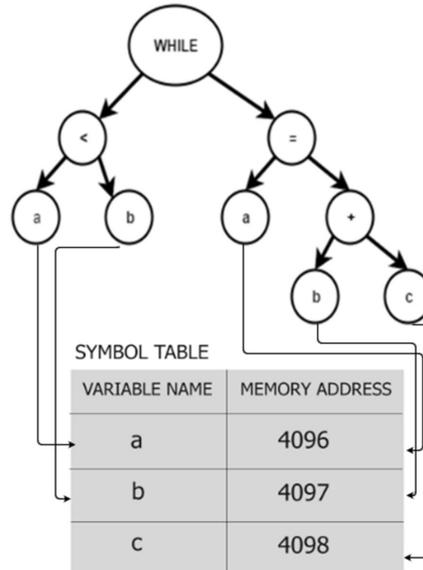

- Transforms abstract syntax tree to instructions for a particular computer architecture

### Input Program

```

while (a < b) do
  a = b + c
end while
  
```

### CODE GENERATION
